Influence of thermodynamics on ORC turbines

Unconventional thermodynamic expansion \rightarrow unconventional turbines:

- High expansion ratios \rightarrow large passage area ratio
- Small enthalpy drops → low number of stages / low peripheral speed
- Fluid (and flow..) complexity \rightarrow low speed of sound, transonic/supersonic turbines

Scientific and technical issues

- Supersonic efflux of dense gases still under study
 - \rightarrow influence on turbine efficiency and design criteria
- State-of-art modelling tools necessary for reliable predictions
 - → advanced **real-gas** models coupled with **CFD**

Implementation of advanced modelling techniques into present-day design tools for effective turbine design

M. Pini et al. – Preliminary design of a centrifugal turbine for ORC applications

Outline

Survey on turbine architecture

Design methodology

Design exercise of a multi-stage centrifugal turbine

Conclusions and future works

Turbine architecture

Several architectures are possible

Axial turbines

Centripetal turbines (radial inflow)

Centrifugal turbines (radial outflow):

- ✓ Counter-rotating (Ljiunstrom)
- ✓ Fixed-rotating centrifugal turbine already suggested by Macchi, VKI LS 1977 and Gaia et al., 1978

The centrifugal fixed-rotating turbine

Advantages

- passage area naturally increases along the expansion process
 → fits with the huge increase of fluid specific volume
- more compact compared to equivalent axial turbines
 - \rightarrow higher number of stages \rightarrow lower M, higher efficiency and flexibility

Main disadvantage:

centrifugal force potential acts against work extraction
 → profile aerodynamics crucial for energy exchange effectiveness

$$L_{eu} = \frac{v_1^2 - v_2^2}{2} + \frac{u_1^2 - u_2^2}{2} - \frac{w_1^2 - w_2^2}{2}$$
Negative term (u₂ > u₁) Reduction of work

M. Pini et al. – Preliminary design of a centrifugal turbine for ORC applications

Outline

- Survey on turbine architecture
- Design methodology
- Design exercise of a multi-stage centrifugal turbine
- Conclusions and future works

Overview on design strategy

Difficult task due to the thermodynamic complexity, and transonic flow **Specific turbine design**, depending on fluid and thermodynamic conditions

Design techniques:

- ✓ 1D mean-line method, still used, suited for initial design and optimization
- \checkmark CFD simulations, three dimensional, steady or unsteady, for blade definition
- ✓ Necessity of a bridge between 1D and 3D approach: throughflow method
 → axisymmetric assumption, including losses, flow deflection and blade blockage: define the 'mean-surface' of the flow across the whole machine
 → effects of shocks, post-expansion, annulus boundary layers and flaring are included

M. Pini et al. – Preliminary design of a centrifugal turbine for ORC applications

The 1D mean-line code

- Based on mass conservation, energy balance, estimate of polytropic index
- Criteria to divide the expansion ratio across the stages and blade rows (χ)
- Geometrical assumptions: inlet h/D, discharge blade angles
- Blade span along the machine computed through mass conservation (choking)
- Work exchange computed from velocity triangles
- Entropy production predicted by **loss correlation** (es. Soderberg, Traupel, Craig&Cox)

Code main features

- \checkmark Applicable to the design of axial and radial turbines
- Coupled with FluidProp (Prof. Colonna, TU Delft)
 for thermodynamic properties calculation
- ✓ Directly connected with the throughflow solver

M. Pini et al. – Preliminary design of a centrifugal turbine for ORC applications

Throughflow concept

Multistage LP axial turbine: fully 3D unsteady: CFD affordable but with very high computational cost (no optimization)

Axisymmetric flow assumption

2D problem: very fast hours → minutes

Intrinsically suitable for optimization

M. Pini et al. – Preliminary design of a centrifugal turbine for ORC applications

CFD-based throughflow model

Axisymmetric inviscid model with volume forces: deflection (L), losses (D)

$$\frac{\partial \boldsymbol{u}}{\partial t} + \frac{\partial \boldsymbol{f}^x}{\partial x} + \frac{1}{r} \frac{\partial (r\boldsymbol{f}^r)}{\partial r} + \frac{1}{r} \boldsymbol{s}^r + \frac{1}{b} \frac{\partial b}{\partial x} \boldsymbol{f}^x + \frac{1}{b} \frac{\partial b}{\partial x} \boldsymbol{f}^r + \boldsymbol{s}^b = \boldsymbol{s}^v$$

$$\boldsymbol{u} = \begin{bmatrix} \rho \\ \rho e_0 \\ \rho v_x \\ \rho v_r \\ \rho v_r \\ \rho v_\theta \end{bmatrix}, \quad \boldsymbol{f}^x = \begin{bmatrix} \rho v_x \\ \rho h_0 v_x \\ \rho v_x^2 + P \\ \rho v_r v_x \\ \rho v_r v_x \\ \rho v_\theta v_x \end{bmatrix}, \quad \boldsymbol{f}^r = \begin{bmatrix} \rho v_r \\ \rho h_0 v_r \\ \rho v_x v_r \\ \rho v_x v_r \\ \rho v_r^2 + P \\ \rho v_\theta v_r \end{bmatrix} \qquad \boldsymbol{b}(x,r) = \frac{N[\theta_p(x,r) - \theta_s(x,r)]}{2\pi}$$

$$\boldsymbol{s}^{r} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ -(\rho v_{\theta}^{2} + P) \\ \rho v_{r} v_{\theta} \end{bmatrix}, \quad \boldsymbol{s}^{b} = \begin{bmatrix} 0 \\ 0 \\ -P \partial b / \partial x \\ -P \partial b / \partial r \\ 0 \end{bmatrix}, \quad \boldsymbol{s}^{v} = \begin{bmatrix} 0 \\ \rho(\mathbf{L} + \mathbf{D}) \cdot \omega r \mathbf{e}_{\theta} \\ \rho(\mathbf{L} + \mathbf{D}) \cdot \mathbf{e}_{x} \\ \rho(\mathbf{L} + \mathbf{D}) \cdot \mathbf{e}_{r} \\ \rho(\mathbf{L} + \mathbf{D}) \cdot \mathbf{e}_{\theta} \end{bmatrix}$$

$$\mathbf{L} = L\mathbf{n}_g \implies L = L(\mathbf{u}) = -K\mathbf{w} \cdot \mathbf{n}_g = -K\left(\mathbf{v} - \omega r\mathbf{e}_\theta\right) \cdot \mathbf{n}_g$$
$$\mathbf{D} = -D\mathbf{t} = -D\frac{\mathbf{w}}{||\mathbf{w}||} \implies D = T\nabla s \cdot \frac{\mathbf{w}}{||\mathbf{w}||} = T\nabla s \cdot \mathbf{t}$$

M. Pini et al. – Preliminary design of a centrifugal turbine for ORC applications

Throughflow package

Numerical scheme

- Implemented as an extension of the *zFlow* code (Prof. Rebay, Univ. of Brescia)
- Based on hybrid FE/FV formulation, uses fully implicit time-marching methods
 → very efficient and accurate computational model (especially for 2D problems)
- Coupled with FluidProp (Prof. Colonna, TU Delft) for thermodynamic properties
 → accurate treatment to handle arbitrary EoS (thus to deal with organic fluids)

Blade modeler & grid generator

- Throughflow solver integrated by a blade modeler with mesh generator
- Blade mean line and blockage factor managed through a generalized blade modeler
- Structured multi-block mesh generator for axial, radial and mixed-flow machines

Outline

- 1. The radial-outflow turbine
- 2. Turbine design method

3. Design exercise of a multi-stage centrifugal turbine

4. Conclusions and future works

M. Pini et al. – Preliminary design of a centrifugal turbine for ORC applications

Design exercise: throughflow model

From lumped-parameter mean-line to continuous mean-blade-surface

- Design of meridional channel
 - \rightarrow blade span evolution along the machine from 1D model
 - \rightarrow relevant risk of separation close to the endwalls (gaps act as vaneless diffusers)
 - \rightarrow constant flaring angle in each bladed region, inter-row gaps as small as possible
- Definition of the blade shape: mean line and blade thickness
 - \rightarrow basic 2D profiles developed for axial turbines
 - \rightarrow profile deformation to match in/out design blade angles
 - \rightarrow conformal transformations in polar coordinates to conserve blade angles

Design exercise: throughflow calculation

Soderberg correlation for core flow + annulus boundary layer loss model

21 (span) x 400 (stream) grid, computational time ~5 min

Flow distribution on the whole meridional surface Maximum abs/rel Mach number target nearly confirmed (1.1) Significant deviations from 1D model in the last stages

Design exercise: throughflow calculation

Streamwise evolution of thermodynamic quantities

M. Pini et al. – Preliminary design of a centrifugal turbine for ORC applications

Conclusions and future works

- Multistage centrifugal turbine architecture considered
- Design methodology for multistage ORC turbines proposed, based on:
 mean-line code
 - CFD-based throughflow model
- Design exercise for a 'mainstream' ORC turbine (P~1.3 MW, Pt = 10bar, Tt=270°C)
 → 6 stages, 3000 rpm, R = 0.7 m, η ~ 89%
- Throughflow model: 1D integral data corrections, large spanwise gradients
- Future work will move mainly in three-directions:
 - \rightarrow blade-to-blade calculations to update loss and slip factor correlations
 - \rightarrow unsteady calculations to investigate blade-row interaction (very small gaps!)
 - \rightarrow coupling with optimization methods to determine the optimal streamsurface

THANK YOU!
